Handout 11
Energy Bands in Graphene: Tight Binding and the Nearly Free Electron Approach

In this lecture you will learn:

• The tight binding method (contd…)
• The $\pi$-bands in graphene

Graphene and Carbon Nanotubes: Basics

• Graphene is a two dimensional single atomic layer of carbon atoms arranged in a Honeycomb lattice (which is not a Bravais lattice)
• The underlying Bravais lattice is shown by the location of the black dots and is a hexagonal lattice
• There are two carbon atoms per primitive cell, A and B (shown in blue and red colors, respectively)
• Graphene can be rolled into tubes that are called carbon nanotubes (CNTs)

ECE 407 – Spring 2009 – Farhan Rana – Cornell University
Graphene: Sp2 Hybridization

Sp2 hybridization in carbon:

- All carbon atoms are all sp2 hybridized (one 2s orbital together with the 2px and the 2py orbitals generate three sp2 orbitals).
- All sp2 orbitals form σ-bonds with the sp2 orbitals of the neighboring carbon atoms.
- The bonding orbital associated with each σ-bond is occupied by two electrons (spin-up and spin-down).
- There is one electron per carbon atom left in the 2pz orbital.

Graphene: 2pz orbitals

π-bonding:

- Each carbon atom contributes one 2p_2-orbital that participates in bonding.

⇒ Each primitive cell contributes two 2p_2-orbitals that participate in bonding.

- The 2p_2 orbital stick out of the plane of the chain and form π-bonds with neighboring 2p_2 orbitals.
- The π-bonding results in energy bands (π-bands) that we will study via tight binding.
Graphene: Some Useful Vectors

Basis vectors:

\[ \mathbf{d}_1 = \frac{a}{2\sqrt{3}} \hat{x}, \quad \mathbf{d}_2 = \frac{a}{2\sqrt{3}} \hat{x} \]

Nearest neighbor vectors:

\[ \mathbf{n}_1 = \frac{a}{\sqrt{3}} \hat{x}, \quad \mathbf{n}_2 = \frac{a}{\sqrt{3}} \left( -\frac{1}{2} \hat{x} + \frac{\sqrt{3}}{2} \hat{y} \right), \quad \mathbf{n}_3 = \frac{a}{\sqrt{3}} \left( -\frac{1}{2} \hat{x} - \frac{\sqrt{3}}{2} \hat{y} \right) \]

These will be useful for writing the final solution in a compact form.

Graphene: Tight Binding Solution

• Each basis atom contributes one \(2p_z\)-orbital that participates in bonding

⇒ Each primitive cell contributes two \(2p_z\)-orbitals that participate in bonding

\[ \phi_{pZA}(\mathbf{r}) \leftrightarrow E_p \quad \phi_{pZB}(\mathbf{r}) \leftrightarrow E_p \]

One can then write the trial tight-binding solution for wavevector \( \mathbf{k} \) as:

\[ \psi_k(\mathbf{r}) = \sum_m \frac{e^{i \mathbf{k} \cdot \mathbf{R}_m}}{\sqrt{N}} \left[ c_{pZA}(k) e^{i \mathbf{k} \cdot \mathbf{d}_1} \phi_{pZA}(\mathbf{r} - \mathbf{R}_m - \mathbf{d}_1) + c_{pZB}(k) e^{i \mathbf{k} \cdot \mathbf{d}_2} \phi_{pZB}(\mathbf{r} - \mathbf{R}_m - \mathbf{d}_2) \right] \]
Plug the solution into the Schrödinger equation:
\[ \hat{H} \psi_k(r) = E(k) \psi_k(r) \]

And then, one by one, multiply by from the left by the bra's corresponding to every orbital in one primitive cell to generate as many equations as the number of orbitals per primitive cell.

**Step 1:**
Multiply the equation with \( \langle \phi_{pzA} | \hat{r} \rangle \) and:
- keep the energy matrix elements for orbitals that are nearest neighbors, and
- assume that the orbitals on different atoms are orthogonal

\[
E_p \ c_{pzA}(k) - V_{ppx} \left( e^{-i \mathbf{k} \cdot \mathbf{n}_1} + e^{-i \mathbf{k} \cdot \mathbf{n}_2} + e^{-i \mathbf{k} \cdot \mathbf{n}_3} \right) c_{pzB}(k) = E(k) c_{pzA}(k)
\]

Notice that the final result can be written in terms of the nearest neighbor vectors.

**Step 2:**
Multiply the equation with \( \langle \phi_{pzB} | \hat{r} \rangle \) and:
- keep the energy matrix elements for orbitals that are nearest neighbors, and
- assume that the orbitals on different atoms are orthogonal

\[
E_p \ c_{pzB}(k) - V_{ppx} \left( e^{-i \mathbf{k} \cdot \mathbf{n}_1} + e^{-i \mathbf{k} \cdot \mathbf{n}_2} + e^{-i \mathbf{k} \cdot \mathbf{n}_3} \right) c_{pzA}(k) = E(k) c_{pzB}(k)
\]

Notice that the final result can be written in terms of the nearest neighbor vectors.
Graphene: Tight Binding Solution

Write the equations obtained in a matrix form:

\[
\begin{bmatrix}
E_p & -V_{pp\pi} f(k) \\
-V_{pp\pi} f^*(k) & E_p
\end{bmatrix}
\begin{bmatrix}
c_{pzA}(k) \\
c_{pzB}(k)
\end{bmatrix}
= E(k)
\begin{bmatrix}
c_{pzA}(k) \\
c_{pzB}(k)
\end{bmatrix}
\]

Where the function \( f(k) \) is:

\[
f(k) = \left( e^{i \cdot \hat{k} \cdot \hat{n}_1} + e^{i \cdot \hat{k} \cdot \hat{n}_2} + e^{i \cdot \hat{k} \cdot \hat{n}_3} \right)
\]

Solutions are:

\[
E(k) = E_p \pm V_{pp\pi} |f(k)|
\]

And the corresponding eigenvectors are:

\[
\begin{bmatrix}
c_{pzA}(k) \\
c_{pzB}(k)
\end{bmatrix}_+ = \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & -f^*(k) |f(k)| \end{bmatrix}
\]

\[
\begin{bmatrix}
c_{pzA}(k) \\
c_{pzB}(k)
\end{bmatrix}_- = \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & f^*(k) |f(k)| \end{bmatrix}
\]

Graphene: \( \pi \)-Energy Bands

- Bandgaps open at the M-points between the first and the second bands
- No bandgaps open at the K-points and the K'-points
- In the homeworks you showed (using nearly free electron approach) that bandgaps can open at the K-points (or K'-points) if the inversion symmetry is broken
Graphene: $\pi$-Energy Bands

- Since graphene has two electrons per primitive cell contributing to $\pi$-bonding, the lower $\pi$-band will be completely filled at $T \approx 0K$
- The location of Fermi level near $T \approx 0K$ is shown by the dashed curve

In generating the plots I chose energy zero such that:

$$E_p = 0$$

And for graphene:

$$V_{pp\pi} = 3.0 \text{ eV}$$

Graphene: A Comparison of NFEA and TB

Scale normalized to:

$$\frac{\hbar^2}{2m} \left( \frac{1}{a} \right)^2$$

and offset by $V_o$

To compare the nearly free electron approach (NFEA) to tight-binding (TB) I assumed the DC potential in NFEA to be:

$$V_o = E_p - 3V_{pp\pi}$$

And in graphene:

$$V_{pp\pi} = 3.0 \text{ eV}$$
