Abstract The latter part of the twentieth century saw the lean production paradigm positively impact many market sectors ranging from automotive through to construction. In particular there is much evidence to suggest that level scheduling combined with the elimination of muda has successfully delivered a wide range of products to those markets where cost is the primary order winning criteria. However, there are many other markets where the order winner is availability. This has led to the emergence of the agile paradigm typified by “quick response” and similar initiatives. Nevertheless, “lean” and “agile” are not mutually exclusive paradigms and may be married to advantage in a number of different ways. This paper explores ways in which hybrid strategies can be developed to create cost-effective supply chains and proposes an integrated manufacture/logistics model for enabling the essential infrastructure.

Introduction
A key feature of present day business is the idea that it is supply chains that compete, not companies (Christopher, 1992), and the success or failure of supply chains is ultimately determined in the marketplace by the end consumer. Getting the right product, at the right price, at the right time to the consumer is not only the linchpin to competitive success but also the key to survival. Hence, customer satisfaction and marketplace understanding are crucial elements for consideration when attempting to establish a new supply chain strategy. Only when the requirements and constraints of the marketplace are understood can an enterprise attempt to develop a strategy that will meet the needs of both the supply chain and the end customer.

Supply chain performance improvement initiatives strive to match supply to demand thereby driving down costs simultaneously with improving customer satisfaction. This invariably requires uncertainty within the supply chain to be reduced as much as practicable so as to facilitate a more predictable upstream demand (Mason-Jones et al., 1999). Sometimes, however, uncertainty is impossible to remove from the supply chain due to the type of product involved. For example, if a product is highly fashionable then by its intrinsic nature its demand will be unpredictable. Hence, specific supply chains are faced with the situation where they have to accept uncertainty but need to develop a strategy that enables them to still match supply and demand.

Significant interest has been shown in recent years in the idea of “lean manufacturing” (Womack et al., 1990), and the wider concepts of the “lean
enterprise” (Womack and Jones, 1996). The focus of the lean approach has essentially been on the elimination of waste or muda. The upsurge of interest in lean manufacturing can be traced to the Toyota Production Systems with its focus on the reduction and elimination of waste (Ohno, 1988). However, the origins of lean manufacture are certainly visible in Spitfire aircraft production in the UK in the Second World War, and Keiretsu dates back to the US automotive industry in 1915 (Towill et al., 2000). In the context of the present paper, it has been argued elsewhere (Christopher, 2000) that lean concepts work well where demand is relatively stable and hence predictable and where variety is low. Conversely, in those contexts where demand is volatile and the customer requirement for variety is high, a much higher level of agility is required.

Agility is a business-wide capability that embraces organisational structures, information systems, logistics processes and in particular, mindsets. A key characteristic of an agile organisation is flexibility. In that respect, the origins of agility as a business concept lie partially in flexible manufacturing systems. Initially it was thought that the route to manufacturing flexibility was through automation to enable rapid changeovers (i.e. reduced set-up times) and thus enable a greater responsiveness to changes in product mix or volume. Later this idea of manufacturing flexibility was extended into the wider business context (Nagel and Dove, 1991) and the concept of agility as an organisational orientation was born.

Naylor et al. (1999) provide a useful definition of the two paradigms we are considering as follows:

*Agility* means using market knowledge and a virtual corporation to exploit profitable opportunities in a volatile marketplace.

*Leanness* means developing a value stream to eliminate all waste including time, and to enable a level schedule.

It is the purpose of the present paper to show the various ways in which these paradigms may be combined to enable highly competitive supply chains capable of winning in a volatile and cost-conscious environment. In doing so we shall emphasise the important differences between the two paradigms, and also how one may benefit from the implementation of the other. As Warnecke and Huser (1995) forcefully point out, there is a need in all change management programmes to consider the intellectual as well as the operational needs of the supply chain. Hence, the development and description of our Integrated Model for enabling the agile enterprise based upon the concept of a seamless connection between manufacture and logistics.

The cyclical nature of market winners and market qualifiers

Hill (1993) has earlier developed the concept of “order qualifiers” and “order winners” against which it is advocated that manufacturing strategy should be determined. As these labels suggest, it is important for every business to understand what the baseline is for entering into a competitive arena – these are the “order qualifiers”. Actually to win the order requires specific capabilities and these Hill termed the “order winners”. The definition of order qualifiers and
order winners then logically leads to the specification of the appropriate manufacturing strategy. We can borrow from these important ideas to develop a wider supply chain oriented concept of “market qualifiers” and “market winners”. The notion here is that to be truly competitive requires not just the appropriate manufacturing strategy, but rather an appropriate holistic supply chain strategy.

The connection between these ideas of “qualifiers” and “winners” and “lean” and “agile” is critical. At its simplest the lean paradigm is most powerful when the winning criterion is cost; however, when service and customer value enhancement are prime requirements for market winning then the likelihood is that agility will become the critical dimension. Figure 1 illustrates the crucial differences in focus between the lean and agile paradigm depending upon the market qualifiers and the market winners based upon the work of Mason-Jones et al. (2000).

It is in the nature of competition that last year’s market winner will be replaced this year by a former market qualifier (Johansson et al., 1993). This can be illustrated in the context of the lean and agile paradigms by studying the migration of the operation of the personal computer supply chain. Thus Table I describes the transition over a 15-20 year period from product driven to market orientated to market driven and finally through to individual customer driven enterprise (Christopher and Towill, 2000). During that change the market winner has rotated between quality, cost, availability and lead-time. But at any one point in time the other performance metrics remain market qualifiers which cannot be prejudiced if business is to continue to be won.

**Attributes of lean and agile supply**
Whereas quality, service level, and lead-time are market qualifiers for lean supply, with the market winner then being cost, the latter benchmark is merely an important qualifier in agile supply (Christopher and Towill, 2000). Fisher (1997) makes a similar point which is that where the risk of obsolescence and/or the cost of a stockout is high relative to the cost of production and distribution, then a different supply chain solution is required. This leads to the conclusion that the total costs for the product delivery process (PDP) are:

**Source:** Mason-Jones et al. (2000)
Supply chain total PDP costs = physical PDP costs + marketability costs

where:

- Physical costs includes all production, distribution, and storage costs.
- Marketability costs includes all obsolescence and stockout costs.

The first cost source (PDP) dominates lean supply whereas the second cost source (marketability costs) dominates agile supply. Note that lost sales are gone for ever in the agile supply chain whether the cause is due to stockouts or to obsolescence. This is because it is an extremely harsh and competitive marketplace with little brand loyalty. As we shall see later, the requirement is for the product to be both affordable and available. We shall now undertake a detailed comparison of lean and agile supply by comparing specific attributes which highlight the specific problems to be overcome in enabling the appropriate business strategy to be adopted.

Both agility and leanness demand high levels of product quality. They also require minimisation of total lead-times defined as the time taken from a customer raising a request for a product or service until it is delivered. Total lead-time has to be minimised to enable agility, as demand is highly volatile and thus difficult to forecast. If a supply chain has long end-to-end lead-time then it will not be able to respond quickly enough to exploit marketplace demand. Furthermore effective engineering of cycle time reduction always leads to significant bottom line improvements in manufacturing costs and productivity (Towill, 1996).

Lead-time needs to be reduced in lean manufacturing as by definition excess time is waste and leanness calls for the elimination of all waste. The essence of the difference between leanness and agility in terms of the total value provided

to the customer is that service level (availability) is the critical factor calling for agility whilst cost, and hence the sales price, is clearly linked to leanness. However, whereas the total cycle time compression paradigm (Towill, 1996), when effectively implemented, is a sufficient condition for achieving lean production, it is only one necessary condition for enabling agile supply.

Table II illustrates the comparison of attributes between lean and agile supply. In the volatile unpredictable marketplace for “fashion” goods, both stockout and obsolescence costs are punitive. Consequently the purchasing policy moves from placing orders upstream for products moving in a regular flow to that of assigning capacity to finalise products in rapid response mode. As Fisher et al. (1994) have indicated this means forecasting via “intelligent” consultation so as to maximise inputs from “rich” marketplace insider sources.

**Practical ways of marrying the lean and agile paradigms**

As we have indicated, there are a number of common elements between the lean and agile paradigms. Provided the whole concept is fully thought through and properly managed, lean and agile businesses can co-exist, even when on the same site and with some limited rotation of personnel (Aitken, 2000). Here are three proven ways in which the paradigms have been brought together to provide available and affordable products for the end customer.

*The Pareto curve approach*

Many companies manufacturing or distributing a range of products will find that the Pareto Law will apply and can be exploited to determine supply strategy. Typically an analysis of the business will show that the 80/20 (or similar) rule holds (Koch, 1997). In other words, 80 per cent of total volume will be generated from just 20 per cent of the total product line. The way in which

these 20 per cent are managed should probably be quite different from the way
the remaining 80 per cent are managed. For example it could be argued that the
top 20 per cent of products by volume are likely to be more predictable and
hence they lend themselves to lean principles of manufacturing and
distribution. The slow moving 80 per cent, on the other hand, will typically be
less predictable and will require a more agile mode of management. Figure 2
suggests one generic way in which supply chain strategies may be devised for
the predictable 20 per cent and the more volatile 80 per cent of products.

The de-coupling point approach
A further marrying of the lean and agile paradigms can be achieved through
the creation of a “de-coupling point” using what may be termed strategic
inventory. Here the idea is to hold inventory in some generic or modular form
and only complete the final assembly or configuration when the precise
customer requirement is known. An example is the customised PC (Christopher
and Towill, 2000). This concept of “postponement” is now increasingly widely
employed by organisations in a range of industries (van Hoek, 1998). As shown
in Figure 3, by utilising the concept of postponement, companies may utilise

Figure 2.
The Pareto distribution

Figure 3.
The decoupling point
Design of agile supply chains

lean methods up to the de-coupling point and agile methods beyond it. Companies such as Hewlett-Packard have successfully employed such strategies to enable products to be localised much closer in time to actual demand (Feitzinger and Lee, 1997). However, as Pagh and Cooper (1998) have pointed out, satisfying customer demand may require particular combinations of postponed manufacture and postponed logistics.

A parallel concept to the “material” de-coupling point described above is that of the “information” de-coupling point (Mason-Jones and Towill, 1999). This represents the furthest point upstream to which information on “real” demand flows, i.e. information which has not been distorted by inventory policies such as re-order points and re-order quantities. The ability to base replenishment decisions on real demand clearly contributes to supply chain agility.

Separation of “base” and “surge” demands
Other hybrid strategies that have been employed with success are based upon separating demand patterns into “base” and “surge” elements (Gattorna and Walters, 1996). Figure 4 highlights this distinction together with one possible level scheduling solution where capacity demands are smoothed by intelligent switching of “base” production. Base demand can be forecast on the basis of past history whereby surge demand typically cannot. Base demand can be met through classic lean procedures to achieve economies of scale whereas surge demand is provided for through more flexible, and probably higher cost, processes. Strategies such as these are increasingly being employed in the fashion industry where the base demand can be sourced in low cost countries and the surge demand “topped up” locally nearer to the market. Even though the unit cost of manufacture in local markets will be higher than sourcing in low cost locations, the supply chain advantage can be considerable. Alternatively, arrangements can be made for dealing with both “base” and “surge” demands either by separation in space (via separate production lines) or in time (by using slack periods to produce base stock). This contrasts with the lean concept of “level scheduling”.

![Figure 4. Responding to combinations of “base” and “surge” demands](image)
Well-documented companies employing such strategies include Zara (Christopher, 1998), Benetton (Zuccaro, 1998), and National Bicycle (Fisher et al., 1994). What is particularly important is to relate the strategy throughout the whole supply chain to the needs of the end customer in terms of both affordability and availability.

Whilst these three strategies are complementary rather than mutually exclusive, it is likely that each may work better in certain conditions. A suggested set of appropriate conditions for the application of the three hybrid strategies is presented in Table III.

The three lean/agile hybrid strategies described above confirm that the real focus of supply chain re-engineering should be on seeking ways in which the appropriate combination of lean and agile strategies can be achieved. Our proposed integrated model described below provides the essential infrastructure.

**An integrated approach to supply chain design**

Our contention is that lean methodologies can be a powerful contributor to the creation of agile enterprises. In particular where product ranges can be separated according to volume and variability and/or where the de-coupling concept can be applied, a real opportunity exists for employing hybrid lean/agile strategies. There is also one important sense in which lean precedes agile, and which has been advanced by Victor and Boynton (1998) in the context of moving towards mass customisation. This is because real and effective change requires the mapping and understanding of all the relevant business processes. Thus, in an industrial engineering scenario the lean knowledge base is there to be exploited in enabling further performance improvements including building in agility (Childerhouse et al., 2000).

Figure 5 suggests a three-level framework summarising our view of the agile supply chain. The concept of such a framework was first advocated by Werr et al. (1997). We have found it extremely useful in bringing together the various possibilities.

Table III.

A contingency approach to supply chain strategy choice
strands which contribute to the agile enterprise. In this integrative model, Level 1 represents the key principles that underpin the agile supply chain; rapid replenishment; and postponed fulfilment. Level 2 identifies the individual programmes such as lean production, organisational agility, and quick response which must be implemented in order for the Level 1 principles to be achieved. Level 3 specifies individual actions to be taken to support Level 2 programmes, for example, time compression, information enrichment, and waste elimination. Not all the characteristics shown in Figure 5 may be necessary in any one specific market/manufacturing context, but it is likely that the agile supply chain will embody many of these elements. What is certain is that much of the conventional wisdom concerning manufacturing strategy, supplier relations and distribution will have to be challenged if real agility is to be achieved from within the supply chain.

Rapid replenishment, for example, requires agile suppliers, organisational agility, and a demand driven supply chain (Lowson et al., 1999). Similarly, postponed fulfilment enables the adoption of lean production principles up to the de-coupling point supported by agile capabilities beyond that point (Harrison et al., 1999). Nor must the cultural side be forgotten, since it may be the single biggest barrier to effective change. For example, in moving towards an agile structure in one company in the pharmaceuticals sector, it was found that the anticipated IT problems did not arise. Instead, the real stumbling blocks were the difficulty of creating an understanding of the new system, and the creation of a customer focused culture – in other words people problems (Belk and Steels, 1998). Such reasons could also help explain why successful
industrial implementation of quick response programmes is more patchy than expected (Kotzab, 2000). This is just supporting evidence for the view previously expressed by Andraski (1994) in commenting on the ineffectiveness of many real-world supply chains. He suggested that this is because “80 per cent of problems that arise are due to people, not technology”.

Creating an agile supply clearly requires a number of significant changes to the status quo. Supply chain managers today need also to be change managers – not just managing change within the organisation, but managing change in the way that relationships between organisations are structured. The trend towards the creation of the “virtual” organisation, whilst likely to help achieve agility (Preiss et al., 1995), also requires a high level of co-ordination and management. One way to achieve this co-ordination is to make use of a “pipeline integrator” or, as they have sometimes been termed, a fourth party logistics service provider (4PL). These organisations make use of their expertise and knowledge of managing global supply chains to ensure that even in complex networks a more agile response can be achieved. An example of one company that is taking up this role on behalf of global clients is the Hong Kong-based company Li and Fung (Magretta, 1995). Li and Fung were originally a trading company sourcing and distributing products on behalf of their principals. Over the years they have developed specific expertise and skills that enable them to manage and co-ordinate supply chains. For example, Li and Fung, on behalf of the US retailers, the Limited, will order un-dyed yarn from the yarn supplier, book weaving and dyeing capacity at fabric manufacturers’ facilities and manufacturing capacity at the garment factories; all in advance of the actual requirement being known. As the Limited gets a clearer view of what the requirement is for actual styles, colours and sizes then Li and Fung will issue precise orders and manage the entire supply chain. In the words of the chairman, Victor Fung:

> It would be easier to let the factories worry about securing their own fabric and trim. But then the order would take three months, not five weeks. So to shrink the delivery cycle, I go upstream to organise production. And the shorter production time lets the retailer hold off before having to commit to fashion trend. It’s all about flexibility, response time, small production runs, small minimum order quantities, and the ability to shift direction as the trends move (Magretta, 1995).

**Conclusion**

It is becoming increasingly apparent that competitive advantage derives from the combined capabilities of the network of linked organisations that today we call “the supply chain”. This is a fundamental shift in the traditionally held view of a business model based upon a single firm. It has also become apparent that markets today are increasingly volatile and hence less predictable and so the need for a more agile response has grown.

Putting these two ideas together leads us to the conclusion that a prerequisite for success in these markets will be an agile supply chain.
What we have proposed in this paper is a framework for agility that is contingent upon the context in which the business operates. Thus we have sought to bring together the lean and agile philosophies to highlight the differences in their approach but also to show how they might be combined for greater effect. Increasingly, managers need to understand how market conditions and the wider operating environment will demand not a single off-the-shelf solution, but hybrid strategies which are context specific.
